# PRIMITIVES INTERSECTION WITH CONFORMAL 5D GEOMETRY 

Eduardo Roa<br>eduroam@ldc.usb.ve<br>Víctor Theoktisto<br>vtheok@usb.ve<br>Laboratorio de Computación Gráfica e Interacción<br>Universidad Simón Bolívar, Caracas-VENEZUELA.

#### Abstract

Conformal algebra in conformal geometric space allows for undifferentiated algebraic treatment of first class members such as points, vectors, areas (defined by bivectors) and volumes (defined by trivectors). We have derived a novel unified approach for all types of collisions in conformal space, based in a reformulation of euclidean (3D) collision queries mapped to conformal space (5D). The algebraic formulation of collisions/intersections in conformal space was then prototyped in MATLAB to verify the accuracy of the algorithms for an optimized implementation in GPU

Key words: Conformal Geometry, Collision Detection, Geometric Algebra

## 1 INTRODUCTION

TNtersection among primitives (such as lines, planes and spheres) are core concepts for any collision algorithm, and essential in several Computer Graphics areas such as dynamics, simulation, and graphics rendering [1]. We propose a new unified treatment described herein for all types of collisions: line segment-line segment, line segment-triangle, line segment-sphere, triangle-sphere and sphere-sphere, using Conformal 5D Geometry. A related work [2] shows the implementation in GPU of this algorithms to optimize computation times.

Conformal Geometry uses the geometric algebra framework, which allows for a simple and compact representation of all primitives, adapting easily to the way of how these objects are represented in computer graphics. In its relation to collision detection it has the great advantage of unifying all object intersections by just one formula.

## 2 GEOMETRIC ALGEBRA

O'F the varied approaches for mathematical description in Computer Graphics, the most recent has been the Geometric Algebra formulation, of which a complete description may be found in the work of Dorst [3] [4], and Vince [5].

This algebra has three main operators: the known inner (dot) product ( $\mathbf{x} \cdot \mathbf{y}$ ), the outer (bivector) product $(\mathbf{x} \wedge \mathbf{y})$, and the geometric product ( $\mathbf{x y}$ ). As a vector space, it shares other properties of a vector algebra, such as Euclidean distance, invariance, etc.

Definition 2.1 For vectors $\mathbf{a}$ and $\mathbf{b}$, the outer product $\mathbf{a} \wedge \mathbf{b}$ defines an oriented hyperplane, or bivector, with magnitude the signed area of the counterclockwise parallelogram $\|\mathbf{a} \wedge \mathbf{b}\|=\|\mathbf{a}\|\|\mathbf{b}\| \sin \theta$.

Definition 2.2 The geometric product $\mathbf{a b}$ is a notation for the sum of its inner and outer products.

$$
\begin{equation*}
\mathbf{a b}=\mathbf{a} \cdot \mathbf{b}+\mathbf{a} \wedge \mathbf{b} \tag{1}
\end{equation*}
$$

From these definitions are derived the following algebraic properties

$$
\begin{aligned}
& a \wedge a=0 \\
& (\lambda a) \wedge b=\lambda(a \wedge b), \text { for scalar } \lambda \\
& b \wedge a=-a \wedge b=a \wedge(-b) \\
& a \wedge(b+c)=a \wedge b+a \wedge c \\
& a \cdot b=\frac{1}{2}(a b+b a)
\end{aligned}
$$

$$
\begin{aligned}
& a^{2}=a \cdot a=\|a\|^{2} \\
& (\lambda a) b=\lambda(a b), \text { for scalar } \lambda \\
& b a=b \cdot a+b \wedge a=a \cdot b-a \wedge b \\
& a(b+c)=a b+a c \\
& a \wedge b=\frac{1}{2}(a b-b a)
\end{aligned}
$$

## 3 CONFORMAL GEOMETRY

Conformal Geometry [3, 6] describes an elegant algebraic space for geometric visualization in $\mathbb{R}^{3}$, being homogeneous, supporting point and lines at infinity, preserving angles and distances, and defining concisely points, lines, planes and spheres.

Definition 3.1 A conformal space $\mathbb{R}^{p+1, q+1}$ of $p+1$ positive dimensions and $q+1$ negative dimensions is built from a $\mathbb{R}^{p, q}$. A point $x=u e_{1}+v e_{2}+$ we $e_{3}$ in $\mathbb{R}^{3}$ is a null vector $X=P(x)$ in $\mathbb{R}^{4,1}$ (inner product $X \cdot X=0$, for $X \neq 0$ ), having the orthonormal base $\left\{e_{1}, e_{2}, e_{3}, e, \bar{e}\right\}$.

$$
\begin{array}{lll}
e_{1} \cdot e_{1}=1, & e_{2} \cdot e_{2}=1, \quad e_{3} \cdot e_{3}=1, & n=e+\bar{e}, \quad \bar{n}=e-\bar{e} \\
e \cdot e=1, & \bar{e} \cdot \bar{e}=-1 & X=P(x)=2 x+x^{2} n-\bar{n}
\end{array}
$$

with $n$ and $\bar{n}$ representing null vectors at infinity and at the origin. The primitives shown on Table 1 are derived from these null vectors.

Table 1: Algebraic primitives built in Conformal Geometry 5D

| Primitive | Representation | Geometric Interpretation |
| :--- | :--- | :--- |
| Circle | $\mathrm{C}=P_{1} \wedge P_{2} \wedge P_{3}$ | Defined by three noncollinear points in the perimeter of the circle |
| Line | $\mathrm{L}=P_{1} \wedge P_{2} \wedge n$ | Defined by two nonidentical points on the line plus the point at $\infty$ |
| Sphere | $\mathrm{S}=P_{1} \wedge P_{2} \wedge P_{3} \wedge P_{4}$ | Four noncoplanar points on the surface of the sphere |
| Plane | $\Pi=P_{1} \wedge P_{2} \wedge P_{3} \wedge n$ | Three noncollinear points define a triangle plus the point at $\infty$ |
| Parallelogram | $\mathrm{A}=q_{1} \wedge q_{2}$ | Area formed by two anchored vectors |
| Parallelepiped | $\mathrm{V}=q_{1} \wedge q_{2} \wedge q_{3}$ | Volume formed by three anchored vectors |
| Pseudoscalar | $\mathrm{I}=e_{1} \wedge e_{2} \wedge e_{3} \wedge e \wedge \bar{e}$ | The cannonical rotor for the $\mathbb{R}^{4,1}$ of the conformal space vector base |

Definition 3.2 A k-blade or k -vector is the outer product of $k$ vectors:

$$
\begin{equation*}
v_{1} \wedge v_{2} \wedge \ldots \wedge v_{k-1} \wedge v_{k}=V \in \mathbb{R}^{n, m}, k \leq n+m \tag{2}
\end{equation*}
$$

Definition 3.3 A pseudoscalar is the highest order blade in the space $\mathbb{R}^{n, m}$, represented by $I\left(I^{2}=-1\right)$, and it is analogous to $\mathbf{i}$, the imaginary $90^{\circ}$ counterclockwise canonical rotor of $\mathbb{C}$, the complex plane.

### 3.1 INTERSECTIONS IN CONFORMAL SPACE

Intersections in the conformal geometry model [6] have the advantage of being expressed by just one formula for all primitives, as shown in Table 2.

Definition 3.4 The meet operator $(\checkmark)$ denotes a multivector expression of up to 32 terms (in $\mathbb{R}^{4,1}$ ) representing the geometric intersection of two multivectors. It has the 5-term multivector $\mathbf{I}=\mathbf{e}_{\mathbf{1}} \mathbf{e}_{\mathbf{2}} \mathbf{e}_{\mathbf{3}} \mathbf{e} \mathbf{e}$ as pseudoescalar for that space.

$$
\begin{align*}
& B=(X \vee Y)=(I X) \cdot Y, \quad B^{2}=\|B\|^{2} \\
& B=\beta_{0}+\beta_{e_{1}} e_{1}+\ldots+\beta_{e_{1} e_{2}} e_{1} e_{2}+\ldots+\beta_{e_{1} e_{2} e_{3} e \bar{e}} e_{1} e_{2} e_{3} e \bar{e} \tag{3}
\end{align*}
$$

The work of Roa [7] shows the calculus made for each intersection expressing value for $B^{2}$ :

Table 2: Primitive intersections in $\mathbb{R}^{4,1}$ conformal space

| Primitives | Conformal representation |
| :---: | :---: |
| Line - Plane | $B=\Pi_{1} \vee L_{1}=\left(I \Pi_{1}\right) \cdot L_{1}$ |
| Plane - Plane | $B=\Pi_{1} \vee \Pi_{2}=\left(I \Pi_{1}\right) \cdot \Pi_{2}$ |
| Line - Sphere | $B=S_{1} \vee L_{1}=\left(I S_{1}\right) \cdot L_{1}$ |
| Plane - Sphere | $B=S_{1} \vee \Pi_{1}=\left(I S_{1}\right) \cdot \Pi_{1}$ |
| Sphere - Sphere | $B=S_{1} \vee S_{2}=\left(I S_{1}\right) \cdot S_{2}$ |

if $B^{2} \begin{cases}>0, & \text { intersection at least at two points } \\ =0, & \text { intersection at a tangent point } \\ <0, & \text { primitives do not intersect }\end{cases}$
For spheres (and circles), the radius $\rho$ and the center $\varepsilon$ are given by the expressions $\rho^{\mathbf{2}}=\frac{-\mathbf{S}^{2}}{(\mathbf{S} \wedge \mathbf{n})^{2}}$ and $\varepsilon=\mathbf{S n S}$

## 4 ALGORITHMS

TN computer graphics the intersection of a plane with a sphere or a line with a plane, is straightforward, but not very interesting. More useful are the intersections of triangles with spheres, or line segments with triangles. The following algorithms solve these intersections using the formulas given in Table 2.

### 4.1 LINE SEGMENT-TRIANGLE INTERSECTION

The first step is to determine the intersection of the line containing the segment with the plane containing the triangle in the conformal model. Using the equation [7]:

$$
\begin{aligned}
\mathbf{B} & =\left(\omega_{2} \beta_{3}+\omega_{1} \beta_{4}-\omega_{4} \beta_{1}\right) e_{1} e+\left(\omega_{2} \beta_{3}+\omega_{1} \beta_{4}-\omega_{4} \beta_{1}\right) e_{1} \bar{e}+\left(\omega_{3} \beta_{1}-\omega_{2} \beta_{2}+\omega_{1} \beta_{5}\right) e_{2} e \\
& +\left(\omega_{3} \beta_{1}-\omega_{2} \beta_{2}-\omega_{1} \beta_{5}\right) e_{2} \bar{e}+\left(-\omega_{3} \beta_{3}+\omega_{4} \beta_{2}+\omega_{1} \beta_{6}\right) e_{3} e+\left(-\omega_{3} \beta_{3}+\omega_{4} \beta_{2}+\omega_{1} \beta_{6}\right) e_{3} \bar{e} \\
& +\left(-\omega_{3} \beta_{4}-\omega_{4} \beta_{5}-\omega_{2} \beta_{6}\right) e \bar{e}, \quad \text { with scalar discriminant } \mathbf{B}^{2}=\left(\omega_{3} \beta_{4}+\omega_{4} \beta_{5}+\omega_{2} \beta_{6}\right)^{2}
\end{aligned}
$$

where the $\beta$ 's y $\omega$ 's are the coefficients of the corresponding multivectors $L_{1}$ and $\Pi_{1}$. A nonnegative $B^{2}$ signals a potential collision. If the intersection occurs, it then proceeds to intersect the line segment with each edge of the triangle. Algorithm 1 describes the procedure for calculating the intersection.

\subsection*{4.4 TRIANGLE-SPHERE INTERSECTION}

This algorithm requires three steps. If all three vertexes of the triangle are inside, then there are no intersections. If just one or two points of the triangle are inside the sphere, an intersection exists. If these conditions are not met, then the three points of the triangle are outside the sphere.

We proceed to calculate the intersection in the conformal model, checking the sign of \(B^{2}\) [7], signaling a potential plane-sphere collision. Then we proceed to see if one of the triangle's segments intersects the sphere. If it's affirmative the intersection occurs. However, it may be possible that no segment intersects the sphere and still the intersection exists (see figure 2). To solve this case, we calculate the point \(\mathbf{q}\) (figure 2) whose distance is minimal respect to the center. If that point \(\mathbf{q}\) lies inside the sphere, then the triangle intersects it, otherwise there is no collision. The procedure is indicated in the algorithm 4.

\subsection*{4.5 SPHERE-SPHERE INTERSECTION}

The simplest of all intersections, just verifying the sign of \(B^{2}\) [7] in the last equation of Table 2.

Figure 2: Triangle-Sphere Intersection

\section*{5 CONCLUSIONS}

WE found a elegant procedure to deal with collisions among primitives in a unified manner under the conformal model, based on reformulating the collisions of \(\mathbb{R}^{3}\) euclidean space in the corresponding conformal \(\mathbb{R}^{4,1}\) geometric space. In our algorithms we also used several geometric formulations in \(\mathbb{R}^{3}\) to complement our results. All the algorithms were prototyped and implemented in MATLAB to prove accuracy and correctness. When implemented using the GPU (Graphics Processor Unit) [2], it accounts for greatly accelerated computation times, in some cases allowing for real-time collision detection.

Future work involves simplifying and speeding up even more the calculation of these formulas, and investigating the geometric meaning of each coefficient of the resulting intersection multivector.
